# Introduction to Communication Redundancy

Setting up Communication Redundancy on your network helps protect critical links against failure, protects against network loops, and keeps network downtime at a minimum.

Communication Redundancy allows you to set up *redundant loops* in the network to provide a backup data transmission route in the event that a cable is inadvertently disconnected or damaged. This is a particularly important feature for industrial applications, since it could take several minutes to locate the disconnected or severed cable. For example, if the LAPP switch is used as a key communications component of a production line, several minutes of downtime could cause a big loss in production and revenue. The LAPP switch supports three different protocols to support this communication redundancy function:

- **Turbo Ring** and **Turbo Ring V2**
- **Turbo Chain**
- **Rapid Spanning Tree** and **Spanning Tree Protocols** (IEEE 802.1W/802.1D-2004)

When configuring a redundant ring, all switches on the same ring must be configured to use the same redundancy protocol. You cannot mix the Turbo Ring, Turbo Ring V2, and STP/RSTP protocols on the same ring. The following table lists the key differences between the features of each protocol. Use this information to evaluate the benefits of each, and then determine which features are most suitable for your network.

	<b>Turbo Ring</b>	<b>Turbo Ring V2</b>	<b>Turbo Chain</b>	<b>STP</b>	<b>RSTP</b>
Topology	Ring	Ring	Chain	Ring, Mesh	Ring, Mesh
Fast Ethernet Recovery Time	< 300 ms	< 20 ms	< 20 ms	Up to 30 sec.	Up to 5 sec.

**NOTE** LAPP's managed switches now support three redundancy protocols:

1. **Turbo Ring** is a redundant ring protocol, which has a recovery time of under 300 ms.
2. **Turbo Ring V2** refers to the new generation Turbo Ring, which has a recovery time of under 20 ms for Fast Ethernet ports.
3. **Turbo Chain** is a new redundant protocol with unlimited flexibility that allows you to construct any type of redundant network topology. The recovery time is under 20 ms for Fast Ethernet ports.

In this manual, we use the terminology **Turbo Ring** and **Turbo Ring V2** to differentiate between rings configured for one or the other of these protocols.

The following topics are covered in this chapter:

□ **The Turbo Ring Concept**

□ **Setting up "Turbo Ring" or "Turbo Ring V2"**

- Determining the Redundant Path of a "Turbo Ring" Ring
- Determining the Redundant Path of a "Turbo Ring V2" Ring
- Ring Coupling Configuration
- Dual-Ring Configuration (applies only to "Turbo Ring V2")
- Dual-Homing Configuration (applies only to "Turbo Ring V2")

□ **Configuring "Turbo Ring" and "Turbo Ring V2"**

- Configuring "Turbo Ring"
- Configuring "Turbo Ring V2"

# The Turbo Ring Concept

LAPP supports the proprietary Turbo Ring protocol to optimize communication redundancy and achieve a faster recovery time on the network.

The Turbo Ring and Turbo Ring V2 protocols identify one switch as the **master** of the network, and then automatically block packets from traveling through any of the network’s redundant loops. In the event that one branch of the ring gets disconnected from the rest of the network, the protocol automatically readjusts the ring so that the part of the network that was disconnected can reestablish contact with the rest of the network.

## Setting up “Turbo Ring” or “Turbo Ring V2”

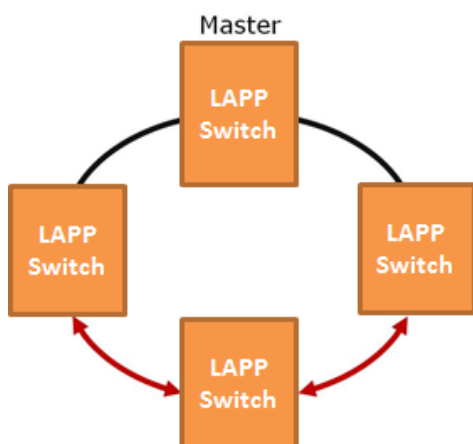

1. Select any two ports as redundant ports.
2. Connect the redundant ports to form the Turbo Ring.

The user does not need to configure any of the switches as the master to use Turbo Ring or Turbo Ring V2. If none of the switches in the ring is configured as the master, then the protocol will automatically assign master status to one of the switches. In fact, the master is only used to identify which segment in the redundant ring acts as the backup path. In the following subsections, we explain how the redundant path is selected for rings configured for Turbo Ring, and Turbo Ring V2.

## Determining the Redundant Path of a “Turbo Ring” Ring

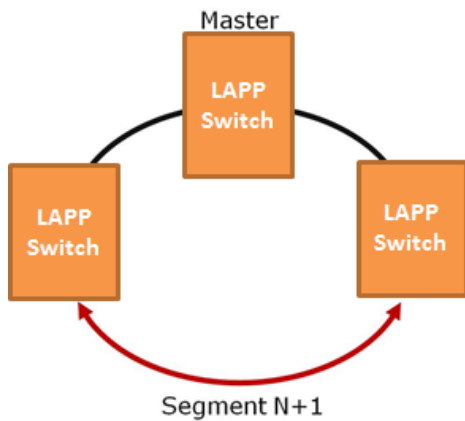

In this case, the redundant segment (i.e., the segment that will be blocked during normal operation) is determined by the number of switches in the ring, and where the ring master is located.

### When the Number of Switches in the Turbo Ring is Even

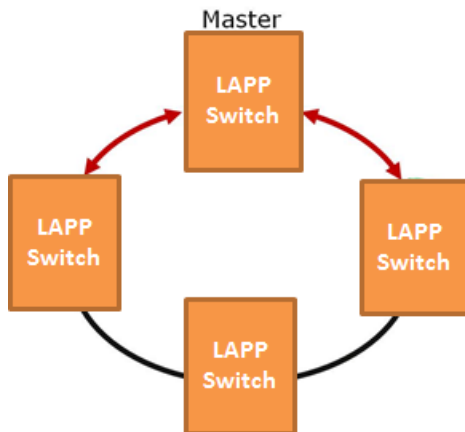

If there are  $2N$  switches (an even number) in the “Turbo Ring” ring, then the backup segment is one of the two segments connected to the  $(N+1)$ st switch (i.e., the switch directly opposite the master).

### When the Number of Switches in the Turbo Ring is Odd

If there are  $2N+1$  switches (an odd number) in the “Turbo Ring” ring, with switches and segments labeled counterclockwise, then segment  $N+1$  will serve as the backup path.  
 For the example shown here,  $N=1$ , so that  $N+1=2$ .

### Determining the Redundant Path of a “Turbo Ring V2” Ring

For a “Turbo Ring V2” ring, the backup segment is the segment connected to the 2nd redundant port on the master.  
 See Configuring “Turbo Ring V2” in the Configuring “Turbo Ring” and “Turbo Ring V2” section below.

### Ring Coupling Configuration

For some systems, it may not be convenient to connect all devices in the system to create one BIG redundant ring, since some devices could be located in a remote area. For these systems, **Ring Coupling** can be used to separate the devices into different smaller redundant rings, but in such a way that they can still communicate with each other.

**ATTENTION**

In a VLAN environment, the user must set **Redundant Port**, **Coupling Port**, and **Coupling Control Port** to join all VLANs, since these ports act as the *backbone* to transmit all packets of different VLANs to different switches.

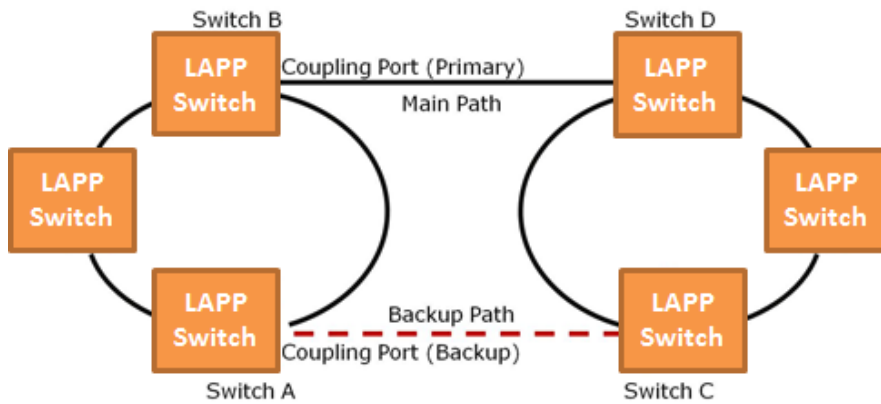

### Ring Coupling for a "Turbo Ring" Ring

To configure the Ring Coupling function for a "Turbo Ring" ring, select two switches (e.g., Switch A and B in the above figure) in the ring, and another two switches in the adjacent ring (e.g., Switch C and D). Decide which two ports in each switch are appropriate to be used as coupling ports, and then link them together. Next, assign one switch (e.g., Switch A) to be the **coupler** and connect the coupler's coupling control port with Switch B (for this example).

The coupler switch (i.e., Switch A) will monitor switch B through the coupling control port to determine whether or not the coupling port's backup path should be recovered.

### Ring Coupling for a "Turbo Ring V2" Ring

Note that the ring coupling settings for a "Turbo Ring V2" ring are different from a "Turbo Ring" ring. For Turbo Ring V2, Ring Coupling is enabled by configuring the **Coupling Port (Primary)** on Switch B, and the **Coupling Port (Backup)** on Switch A only. You do not need to set up a coupling control port, so that a "Turbo Ring V2" ring does not use a coupling control line.

The **Coupling Port (Backup)** on Switch A is used for the backup path, and connects directly to an extra network port on Switch C. The **Coupling Port (Primary)** on Switch B monitors the status of the main path, and connects directly to an extra network port on Switch D. With ring coupling established, Switch A can activate the backup path as soon as it detects a problem with the main path.

 **ATTENTION** Ring Coupling only needs to be enabled on one of the switches serving as the Ring Coupler. The Coupler must designate different ports as the two Turbo Ring ports and the coupling port.

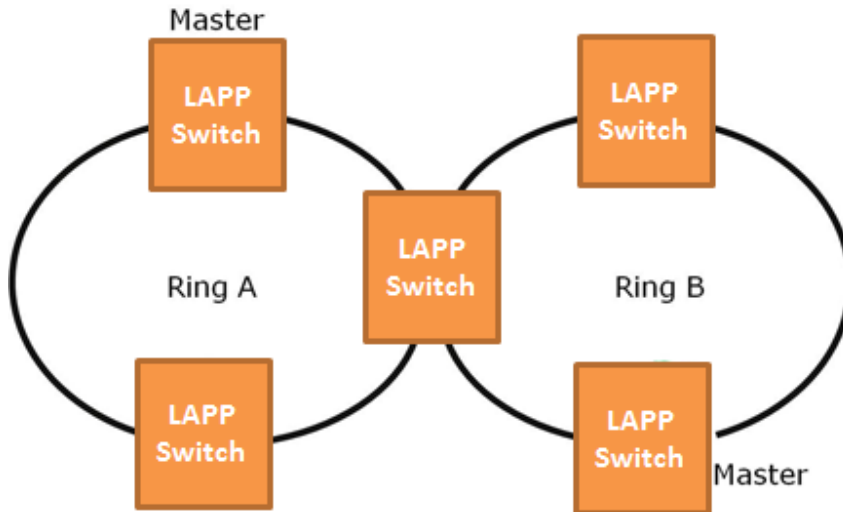

**NOTE** You do not need to use the same switch for both Ring Coupling and Ring Master.

### Dual-Ring Configuration (applies only to “Turbo Ring V2”)

The **dual-ring** option provides another ring coupling configuration, in which two adjacent rings share one switch. This type of configuration is ideal for applications that have inherent cabling difficulties.

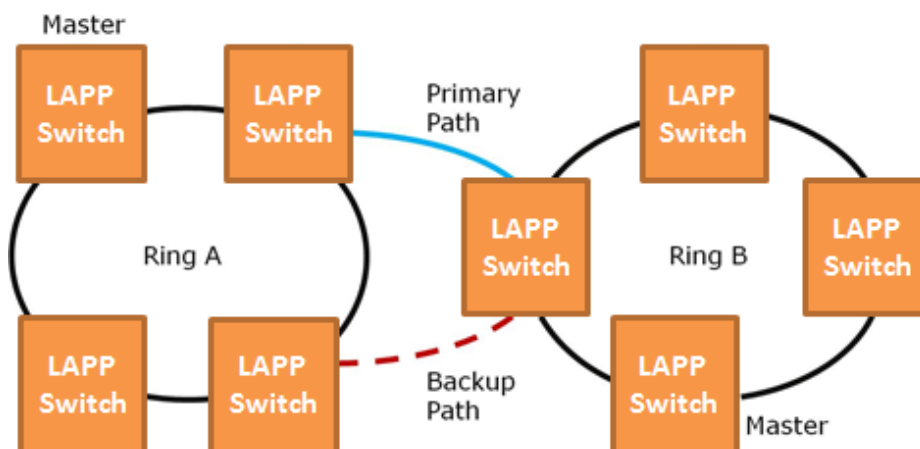

#### Dual-Ring for a “Turbo Ring V2” Ring

### Dual-Homing Configuration (applies only to “Turbo Ring V2”)

The **dual-homing** option uses a single Ethernet switch to connect two networks. The primary path is the operating connection, and the backup path is a back-up connection that is activated in the event that the primary path connection fails.

#### Dual-Homing for a “Turbo Ring V2” Ring

# Configuring “Turbo Ring” and “Turbo Ring V2”

Use the **Communication Redundancy** page to select **Turbo Ring**, **Turbo Ring V2**, or **Turbo Chain**. Note that configuration pages for these three protocols are different.

## Configuring “Turbo Ring”

## Explanation of “Current Status” Items

### Now Active

It shows which communication protocol is in use: **Turbo Ring**, **Turbo Ring V2**, **RSTP**, or **none**.

### Master/Slave

It indicates whether or not this switch is the Master of the Turbo Ring. (This field appears only when Turbo Ring or Turbo Ring V2 modes are selected.)

**NOTE** The user does not need to set the master to use Turbo Ring. If master is not set, the Turbo Ring protocol will assign master status to one of the switches in the ring. The master is only used to determine which segment serves as the backup path.

### Redundant Ports Status (1st Port, 2nd Port)

### Ring Coupling Ports Status (Coupling Port, Coupling Control Port)

The “Ports Status” indicators show **Forwarding** for normal transmission, **Blocking** if this port is connected to a backup path and the path is blocked, and **Link down** if there is no connection.

## Explanation of “Settings” Items

### Redundancy Protocol

Setting	Description	Factory Default
Turbo Ring	Select this item to change to the Turbo Ring configuration page.	None

Turbo Ring V2	Select this item to change to the Turbo Ring V2 configuration page.	
Turbo Chain	Select this item to change to the Turbo Chain configuration page.	
RSTP (IEEE 802.1W/802.1D-2004)	Select this item to change to the RSTP configuration page.	
None	Ring redundancy is not active	

**Set as Master**

Setting	Description	Factory Default
Enabled	Select this switch as Master	Not checked
Disabled	Do not select this switch as Master	

**Redundant Ports**

Setting	Description	Factory Default
1st Port	Select any port of the switch to be one of the redundant ports.	The second to last port
2nd Port	Select any port of the switch to be one of the redundant ports.	The last port

**Enable Ring Coupling**

Setting	Description	Factory Default
Enable	Select this switch as Coupler	Not checked
Disable	Do not select this switch as Coupler	

**Coupling Port**

Setting	Description	Factory Default
Coupling Port	Select any port of the switch to be the coupling port	The fourth from last port

**Coupling Control Port**

Setting	Description	Factory Default
Coupling Control Port	Select any port of the device to be the coupling control port	The third from last port

## Configuring "Turbo Ring V2"

### Communication Redundancy

**Current Status**

Enable Ring Coupling

Coupling Mode Dual Homing

Primary Port 1 Backup Port 1

Activate

**NOTE** When using the Dual-Ring architecture, users must configure settings for both Ring 1 and Ring 2. In this case, the status of both rings will appear under "Current Status."

## Explanation of “Current Status” Items

### Now Active

It shows which communication protocol is in use: **Turbo Ring**, **Turbo Ring V2**, **Turbo Chain**, **RSTP**, or **none**.

### Ring 1/2—Status

It shows **Healthy** if the ring is operating normally, and shows **Break** if the ring’s backup link is active.

### Ring 1/2—Master/Slave

It indicates whether or not this device is the Master of the Turbo Ring. (This field appears only when Turbo Ring or Turbo Ring V2 modes are selected.)

**NOTE** The user does not need to set the master to use Turbo Ring. If master is not set, the Turbo Ring protocol will assign master status to one of the units in the ring. The master is only used to determine which segment serves as the backup path.

### Ring 1/2—1st Ring Port Status

### Ring 1/2—2nd Ring Port Status

The “Ports Status” indicators show **Forwarding** for normal transmission, **Blocking** if this port is connected to a backup path and the path is blocked, and **Link down** if there is no connection.

### Coupling—Mode

It indicates either **None**, **Dual Homing**, or **Ring Coupling**.

### Coupling—Coupling Port status

It indicates either **Primary**, or **Backup**.

## Explanation of “Settings” Items

### Redundancy Protocol

Setting	Description	Factory Default
Turbo Ring	Select this item to change to the Turbo Ring configuration page.	None
Turbo Ring V2	Select this item to change to the Turbo Ring V2 configuration page.	
Turbo Chain	Select this item to change to the Turbo Chain configuration page

None	Ring redundancy is not active	

### Enable Ring 1

Setting	Description	Factory Default
Enabled	Enable the Ring 1 settings	Not checked
Disabled	Disable the Ring 1 settings	Not checked

### Enable Ring 2\*

Setting	Description	Factory Default
Enabled	Enable the Ring 2 settings	Not checked
Disabled	Disable the Ring 2 settings	

Note: You should enable both Ring 1 and Ring 2 when using the Dual-Ring architecture.

### Set as Master

Setting	Description	Factory Default
Enabled	Select this device as Master	Not checked
Disabled	Do not select this device as Master	

**Redundant Ports**

Setting	Description	Factory Default
1st Port	Select any port of the device to be one of the redundant ports.	The second to last port
2nd Port	Select any port of the device to be one of the redundant ports.	The last port

**Enable Ring Coupling**

Setting	Description	Factory Default
Enable	Select this device as Coupler	Not checked
Disable	Do not select this device as Coupler	

**Coupling Mode**

Setting	Description	Factory Default
Dual Homing	Select this item to change to the Dual Homing configuration page	Primary: The fourth from last port Backup: The third from last port
Ring Coupling (backup)	Select this item to change to the Ring Coupling (backup) configuration page	The third from last port
Ring Coupling (primary)	Select this item to change to the Ring Coupling (primary) configuration page	The fourth from last port

**NOTE** Users can also enable Turbo Ring protocols (Turbo Ring or Turbo Ring V2) through the DIP which is located on the outer casing of the switches. For DIP details, please refer to the HIG of ETHERLINE ACCESS M05T/M08T. The default setting is Turbo Ring V2 when you enable it through DIP.

**NOTE** The Turbo Ring DIP Switches located on the outer casing of switches can be used to configure the switches’ Turbo Ring protocols (Turbo Ring or Turbo Ring V2). If the Turbo Ring DIP Switch is enabled from any access interface (web-based UI, console, or Telnet), and the 4th DIP Switch on the switch outer casing is set to **ON**, the Redundancy Protocol will be set automatically to the Turbo Ring protocol based on the version configured in the Turbo Ring DIP Switch page and the corresponding Redundant Ports, Coupling Ports, and Coupling Control Port will be fixed to the assigned factory default port number automatically. In this case, you will not be able to use the web-based UI, console, or Telnet interface to change the status of the DIP Switch and the Communication Redundancy settings will be grayed out in the web browser as shown in the following figure:

**Communication Redundancy**

In addition, those default Redundant Ports, Coupling Ports, and Coupling Control Port will be added automatically to all VLANs (i.e., to act as “Trunk Ports”) if you set the 4th DIP Switch to the “ON” position when the Turbo Ring DIP Switch is enabled. Once you flip the 4th DIP Switch from **ON** to **OFF** when the Turbo Ring DIP Switch is enabled, such default Redundant Ports, Coupling Ports, and Coupling Control Port that were added to all VLANs will be restored to their previous software settings.

**NOTE** If you would like to enable VLAN on any of the last four ports, do not use the fourth DIP switch to activate Turbo Ring. In this case, you should use the Web, Telnet, or Serial console to activate Turbo Ring.

The following topics are covered in this chapter:

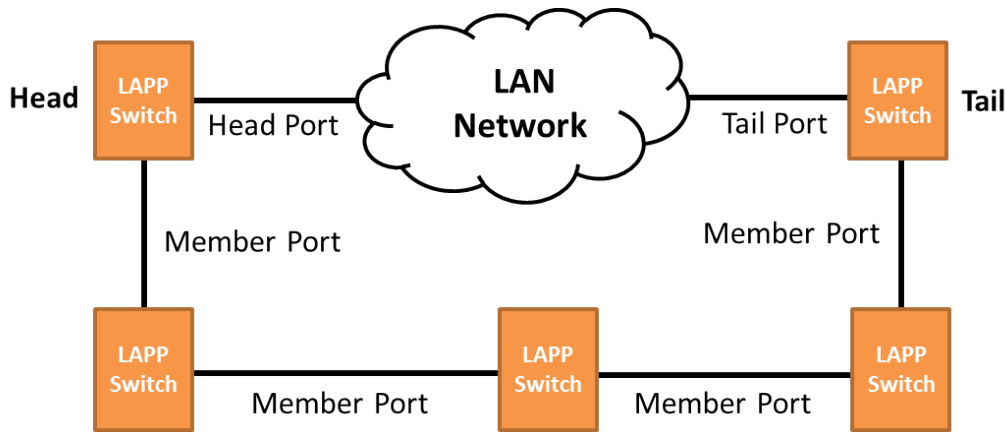

- ❑ **The Turbo Chain Concept**
- ❑ **Setting Up Turbo Chain**
- ❑ **Configuring “Turbo Chain”**
  - Head Switch Configuration
  - Member Switch Configuration
  - Tail Switch Configuration

# The Turbo Chain Concept

Turbo Chain is an advanced software-technology that gives network administrators the flexibility of constructing any type of redundant network topology. When using the "chain" concept, you first connect the Ethernet switches in a chain and then simply link the two ends of the chain to an Ethernet network, as illustrated in the following figure.

Turbo Chain can be used on industrial networks that have a complex topology. If the industrial network uses a multi-ring architecture, Turbo Chain can be used to create flexible and scalable topologies with a fast media-recovery time.

## Setting Up Turbo Chain

1. Select the Head switch, Tail switch, and Member switches.
2. Configure one port as the Head port and one port as the Member port in the Head switch, configure one port as the Tail port and one port as the Member port in the Tail switch, and configure two ports as Member ports in each of the Member switches.
3. Connect the Head switch, Tail switch, and Member switches as shown in the above diagram.

The path connecting to the Head port is the main path, and the path connecting to the Tail port is the backup path of the Turbo Chain. Under normal conditions, packets are transmitted through the Head Port to the LAN network. If any Turbo Chain path is disconnected, the Tail Port will be activated so that packet transmission can continue.

The following topics are covered in this chapter:

- ❑ **The STP/RSTP Concept**
  - What is STP?
  - How STP Works
  - Differences between STP, RSTP
- ❑ **STP Example**
- ❑ **Using STP on a Network with Multiple VLANs**
- ❑ **Configuring STP/RSTP**
- ❑ **Configuration Limits of STP/RSTP**

## The STP/RSTP Concept

Spanning Tree Protocol (STP) was designed to help reduce link failures on a network, and provide an automatic means of avoiding loops. This is particularly important for networks that have a complicated architecture, since unintended loops in the network can cause broadcast storms. LAPP switches' STP feature is disabled by default. To be completely effective, you must enable RSTP/STP on every LAPP switch connected to your network.

Rapid Spanning Tree Protocol (RSTP) implements the Spanning Tree Algorithm and Protocol defined by IEEE 802.1D-2004. RSTP provides the following benefits:

- The topology of a bridged network will be determined much more quickly compared to STP.
- RSTP is backward compatible with STP, making it relatively easy to deploy. For example:
  - Defaults to sending 802.1D style BPDUs if packets with this format are received.
  - STP (802.1D) and RSTP (802.1w) can operate on different ports of the same switch, which is particularly helpful when switch ports connect to older equipment such as legacy switches.

You get essentially the same functionality with RSTP and STP. To see how the two systems differ, see the [Differences between STP and RSTP](#) section in this chapter.

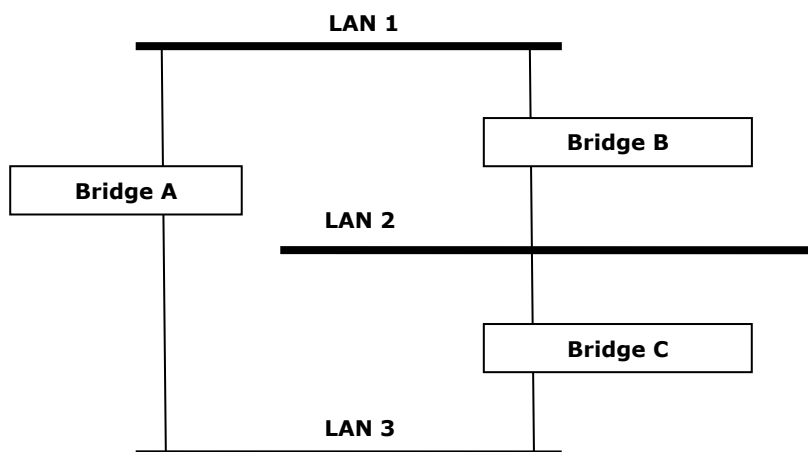

**NOTE** The STP protocol is part of the IEEE Std 802.1D, 2004 Edition bridge specification. The following explanation uses "bridge" instead of "switch."

### What is STP?

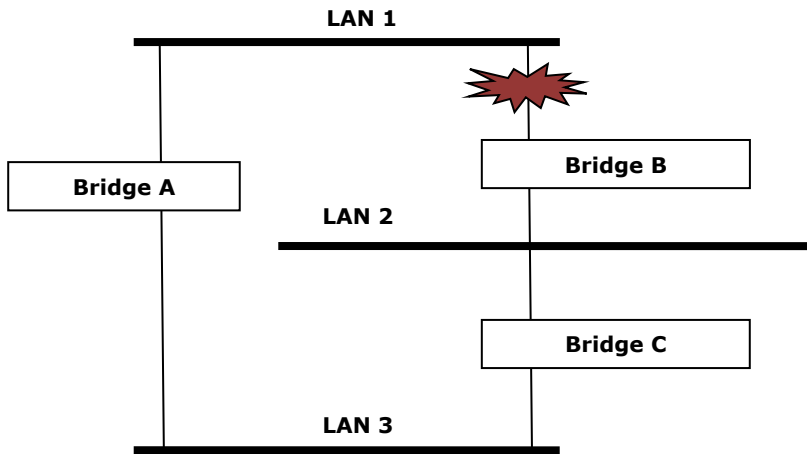

STP (802.1D) is a bridge-based system that is used to implement parallel paths for network traffic. STP uses a loop-detection process to:

- Locate and then disable less efficient paths (i.e., paths that have a lower bandwidth).
- Enable one of the less efficient paths if a more efficient path fails.

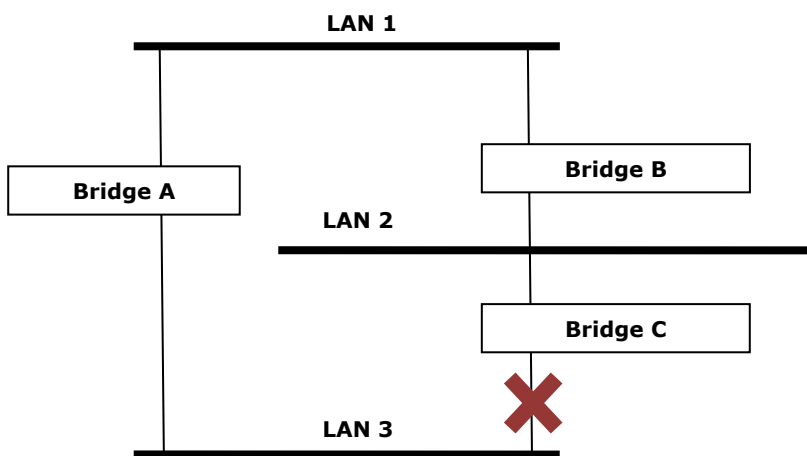

The figure below shows a network made up of three LANs separated by three bridges. Each segment uses at most two paths to communicate with the other segments. Since this configuration can give rise to loops, the network will overload if STP is NOT enabled.

If STP is enabled, it will detect duplicate paths and prevent, or *block*, one of the paths from forwarding traffic. In the following example, STP determined that traffic from LAN segment 2 to LAN segment 1 should flow through bridges C and A since this path has a greater bandwidth and is therefore more efficient.

What happens if a link failure is detected? As shown in next figure, the STP process reconfigures the network so that traffic from LAN segment 2 flows through bridge B.

STP will determine which path between each bridged segment is most efficient, and then assign a specific reference point on the network. When the most efficient path has been identified, the other paths are blocked. In the previous 3 figures, STP first determined that the path through bridge C was the most efficient, and as a result, blocked the path through bridge B. After the failure of bridge C, STP re-evaluated the situation and opened the path through Bridge B.

## How STP Works

When enabled, STP determines the most appropriate path for traffic through a network. The way it does this is outlined in the sections below.

### STP Requirements

Before STP can configure the network, the system must satisfy the following requirements:

- All bridges must be able to communicate with each other. The communication is carried out using Bridge Protocol Data Units (BPDUs), which are transmitted in packets with a known multicast address.
- Each bridge must have a Bridge Identifier that specifies which bridge acts as the central reference point, or Root Bridge, for the STP system—bridges with a lower Bridge Identifier are more likely to be designated as the Root Bridge. The Bridge Identifier is calculated using the MAC address of the bridge and a priority defined for the bridge. For example, the default priority setting of LAPP switches is 32768.
- Each port has a cost that specifies the efficiency of each link. The efficiency cost is usually determined by the bandwidth of the link, with less efficient links assigned a higher cost.

## STP Calculation

The first step of the STP process is to perform calculations. During this stage, each bridge on the network transmits BPDUs. The following items will be calculated:

- Which bridge should be the **Root Bridge**. The Root Bridge is the central reference point from which the network is configured.
- The **Root Path Costs** for each bridge. This is the cost of the paths from each bridge to the Root Bridge.
- The identity of each bridge's **Root Port**. The Root Port is the port on the bridge that connects to the Root Bridge via the most efficient path. In other words, the port connected to the Root Bridge via the path with the lowest Root Path Cost. The Root Bridge, however, does not have a Root Port.
- The identity of the **Designated Bridge** for each LAN segment. The Designated Bridge is the bridge with the lowest Root Path Cost from that segment. If several bridges have the same Root Path Cost, the one with the lowest Bridge Identifier becomes the Designated Bridge. Traffic transmitted in the direction of the Root Bridge will flow through the Designated Bridge. The port on this bridge that connects to the segment is called the **Designated Bridge Port**.

## STP Configuration

After all of the bridges on the network agree on the identity of the Root Bridge, and all other relevant parameters have been established, each bridge is configured to forward traffic only between its Root Port and the Designated Bridge Ports for the respective network segments. All other ports are blocked, which means that they will not be allowed to receive or forward traffic.

## STP Reconfiguration

Once the network topology has stabilized, each bridge listens for Hello BPDUs transmitted from the Root Bridge at regular intervals. If a bridge does not receive a Hello BPDU after a certain interval (the Max Age time), the bridge assumes that the Root Bridge, or a link between itself and the Root Bridge, has ceased to function. This will trigger the bridge to reconfigure the network to account for the change. If you have configured an SNMP trap destination, when the topology of your network changes, the first bridge to detect the change will send out an SNMP trap.

## Differences between STP, RSTP

RSTP is similar to STP, but includes additional information in the BPDUs that allow each bridge to confirm that it has taken action to prevent loops from forming when it decides to enable a link to a neighboring bridge. Adjacent bridges connected via point-to-point links will be able to enable a link without waiting to ensure that all other bridges in the network have had time to react to the change. The main benefit of RSTP is that the configuration decision is made locally rather than network-wide, allowing RSTP to carry out automatic configuration and restore a link faster than STP.

STP and RSTP spanning tree protocols operate without regard to a network's VLAN configuration, and maintain one common spanning tree throughout a bridged network. Thus, these protocols map one loop-free, logical topology on a given physical topology.

## STP Example

The LAN shown in the following figure has three segments, with adjacent segments connected using two possible links. The various STP factors, such as Cost, Root Port, Designated Bridge Port, and Blocked Port are shown in the figure.

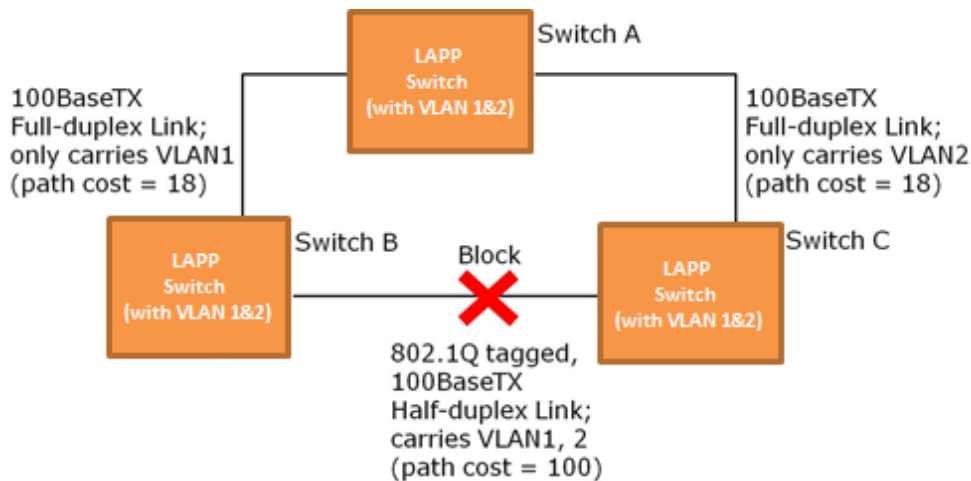

- Bridge A has been selected as the Root Bridge, since it was determined to have the lowest Bridge Identifier on the network.
- Since Bridge A is the Root Bridge, it is also the Designated Bridge for LAN segment 1. Port 1 on Bridge A is selected as the Designated Bridge Port for LAN Segment 1.
- Ports 1 of Bridges B, C, X, and Y are all Root Ports since they are nearest to the Root Bridge, and therefore have the most efficient path.
- Bridges B and X offer the same Root Path Cost for LAN segment 2. However, Bridge B was selected as the Designated Bridge for that segment since it has a lower Bridge Identifier. Port 2 on Bridge B is selected as the Designated Bridge Port for LAN Segment 2.
- Bridge C is the Designated Bridge for LAN segment 3, because it has the lowest Root Path Cost for LAN Segment 3:
  - The route through bridges C and B costs 200 (C to B=100, B to A=100)
  - The route through bridges Y and B costs 300 (Y to B=200, B to A=100)
- The Designated Bridge Port for LAN Segment 3 is port 2 on bridge C.

# Using STP on a Network with Multiple VLANs

IEEE Std 802.1D, 1998 Edition, does not take into account VLANs when calculating STP information—the calculations only depend on the physical connections. Consequently, some network configurations will result in VLANs being subdivided into a number of isolated sections by the STP system. You must ensure that every VLAN configuration on your network takes into account the expected STP topology and alternative topologies that may result from link failures.

The following figure shows an example of a network that contains VLANs 1 and 2. The VLANs are connected using the 802.1Q-tagged link between switch B and Switch C. By default, this link has a port cost of 100 and is automatically blocked because the other switch-to-switch connections have a port cost of 36 (18+18). This means that both VLANs are now subdivided—VLAN 1 on switches A and B cannot communicate with VLAN 1 on switch C, and VLAN 2 on switches A and C cannot communicate with VLAN 2 on switch B.

To avoid subdividing VLANs, all inter-switch connections should be made members of all available 802.1Q VLANs. This will ensure connectivity at all times. For example, the connections between switches A and B, and between switches A and C, should be 802.1Q tagged and carrying VLANs 1 and 2 to ensure connectivity.

## Configuring STP/RSTP

The following figures indicate which Spanning Tree Protocol parameters can be configured. A more detailed explanation of each parameter follows.

### Communication Redundancy

**Current Status**

Root/Not root ---

**Settings**

Redundancy Protocol RSTP (IEEE 802.1D 2004)  
 Bridge Priority 32768 Hello Time 2  
 Forwarding Delay 15 Max Age 20

Port	Enable RSTP	Edge Port	Port Priority	Port Cost	Status
1	<input type="checkbox"/>	Auto	128	200000	---
2	<input type="checkbox"/>	Auto	128	200000	---
3	<input type="checkbox"/>	Auto	128	200000	---
4	<input type="checkbox"/>	Auto	128	200000	---
5	<input type="checkbox"/>	Auto	128	200000	---

Activate

At the top of this page, the user can check the **Current Status** of this function. For RSTP, you will see:

**Now Active:**

It shows which communication protocol is being used—Turbo Ring, RSTP, or neither.

**Root/Not Root**

This field only appears when RSTP mode is selected. The field indicates whether or not this switch is the Root of the Spanning Tree (the root is determined automatically).

At the bottom of this page, the user can configure the **Settings** of this function. For RSTP, you can configure:

**Redundancy Protocol**

Setting	Description	Factory Default
Turbo Ring	Select this item to change to the Turbo Ring configuration page.	None
RSTP (IEEE 802.1W/1D)	Select this item to change to the RSTP configuration page.	None

**Bridge priority**

Setting	Description	Factory Default
Numerical value selected by user	Increase this device’s bridge priority by selecting a lower number. A device with a higher bridge priority has a greater chance of being established as the root of the Spanning Tree topology.	32768

**Forwarding Delay (sec.)**

Setting	Description	Factory Default
Numerical value input by user	The amount of time this device waits before checking to see if it should change to a different state.	15

**Hello time (sec.)**

Setting	Description	Factory Default
Numerical value input by user	The root of the Spanning Tree topology periodically sends out a “hello” message to other devices on the network to check if the topology is healthy. The “hello time” is the amount of time the root waits between sending hello messages.	2

**Max. Age (sec.)**

Setting	Description	Factory Default
Numerical value input by user	If this device is not the root, and it has not received a hello message from the root in an amount of time equal to “Max. Age,” then this device will reconfigure itself as a root. Once two or more devices on the network are recognized as a root, the devices will renegotiate to set up a new Spanning Tree topology.	20

**Enable STP per Port**

Setting	Description	Factory Default
Enable/Disable	Select to enable the port as a node on the Spanning Tree topology.	Disabled

**NOTE** We suggest not enabling the Spanning Tree Protocol once the port is connected to a device (PLC, RTU, etc.) as opposed to network equipment. The reason is that it will cause unnecessary negotiation.

Setting	Description	Factory Default
Auto	1. If the port does not receive a BPDU within 3 seconds, the port will be in the forwarding state. 2. Once the port receives a BPDU, it will start the RSTP negotiation process.	Auto
Force Edge	The port is fixed as an edge port and will always be in the forwarding state	
False	The port is set as the normal RSTP port	

**Port Priority**

Setting	Description	Factory Default
Numerical value selected by user	Increase this port's priority as a node on the Spanning Tree topology by entering a lower number.	128

**Port Cost**

Setting	Description	Factory Default
Numerical value input by user	Input a higher cost to indicate that this port is less suitable as a node for the Spanning Tree topology.	200000

**Port Status**

It indicates the current Spanning Tree status of this port. **Forwarding** for normal transmission, or **Blocking** to block transmission.

## Configuration Limits of STP/RSTP

The Spanning Tree Algorithm places limits on three of the configuration items described previously:

[Eq. 1]:  $1 \text{ sec} \leq \text{Hello Time} \leq 10 \text{ sec}$

[Eq. 2]:  $6 \text{ sec} \leq \text{Max. Age} \leq 40 \text{ sec}$

[Eq. 3]:  $4 \text{ sec} \leq \text{Forwarding Delay} \leq 30 \text{ sec}$

These three variables are further restricted by the following two inequalities:

[Eq. 4]:  $2 \times (\text{Hello Time} + 1 \text{ sec}) \leq \text{Max. Age} \leq 2 \times (\text{Forwarding Delay} - 1 \text{ sec})$

LAPP switch's firmware will alert you immediately if any of these restrictions are violated. For example, setting Hello Time = 5 sec, Max. Age = 20 sec, and Forwarding Delay = 4 sec does not violate Eqs. 1 through 3, but does violate Eq. 4, since in this case,

$2 \times (\text{Hello Time} + 1 \text{ sec}) = 12 \text{ sec}$ , and  $2 \times (\text{Forwarding Delay} - 1 \text{ sec}) = 6 \text{ sec}$ .

You can remedy the situation in many ways. One solution is simply to increase the Forwarding Delay value to at least 11 sec.

*HINT:* Perform the following steps to avoid guessing:

Step 1: Assign a value to **Hello Time** and then calculate the left most part of Eq. 4 to get the lower limit of **Max. Age**.

Step 2: Assign a value to **Forwarding Delay** and then calculate the right most part of Eq. 4 to get the upper limit for **Max. Age**.

Step 3: Assign a value to **Forwarding Delay** that satisfies the conditions
